

# Plant of the Day

*Eichhornia crassipes* (water hyacinth)

Native to South America

Tristylous, clonal

Invasive in Asia, Africa, North America, Australia

Clogs waterways, blocks sunlight and reduces oxygen

(Kills fish, increases mosquitoes)

Uses: furniture, biofuel, bioremediation

Louisiana almost imported hippos to eat it.

# Big Questions

- What are weeds?
- Why can weeds be considered a natural experiment?
- What role does evolution play in invasion?
- Why do invasive species outcompete native species?

“Any plant that crowds out cultivated plants”

“A plant that grows where it is not wanted”

“A plant out of place”

## What is a weed?

“A plant is a weed if...its populations grow entirely or predominantly in situations markedly disturbed by man.”

- HG Baker, 1965

**weed = colonizer / ruderal**

# “Natural experiments” in plant evolution

**Colonization =**  
opportunity for adaptation to novel environments

# “Natural experiments” in plant evolution

## Agricultural weeds

Derived from wild species / other crops

- Adaptation to crop environment
- Opportunities for repeated evolution of weedy forms
- Gene flow / hybridization with progenitors

# Colonizers Associated with Humans

- Weedy:

Human disturbance

- Introduced:

Human-assisted dispersal

-introduced, alien, exotic, non-indigenous, or non-native species

-about 1/4 of vascular plant species in Canada are introduced (1,229 species)

- Invasive:

Rapid spread and dominance

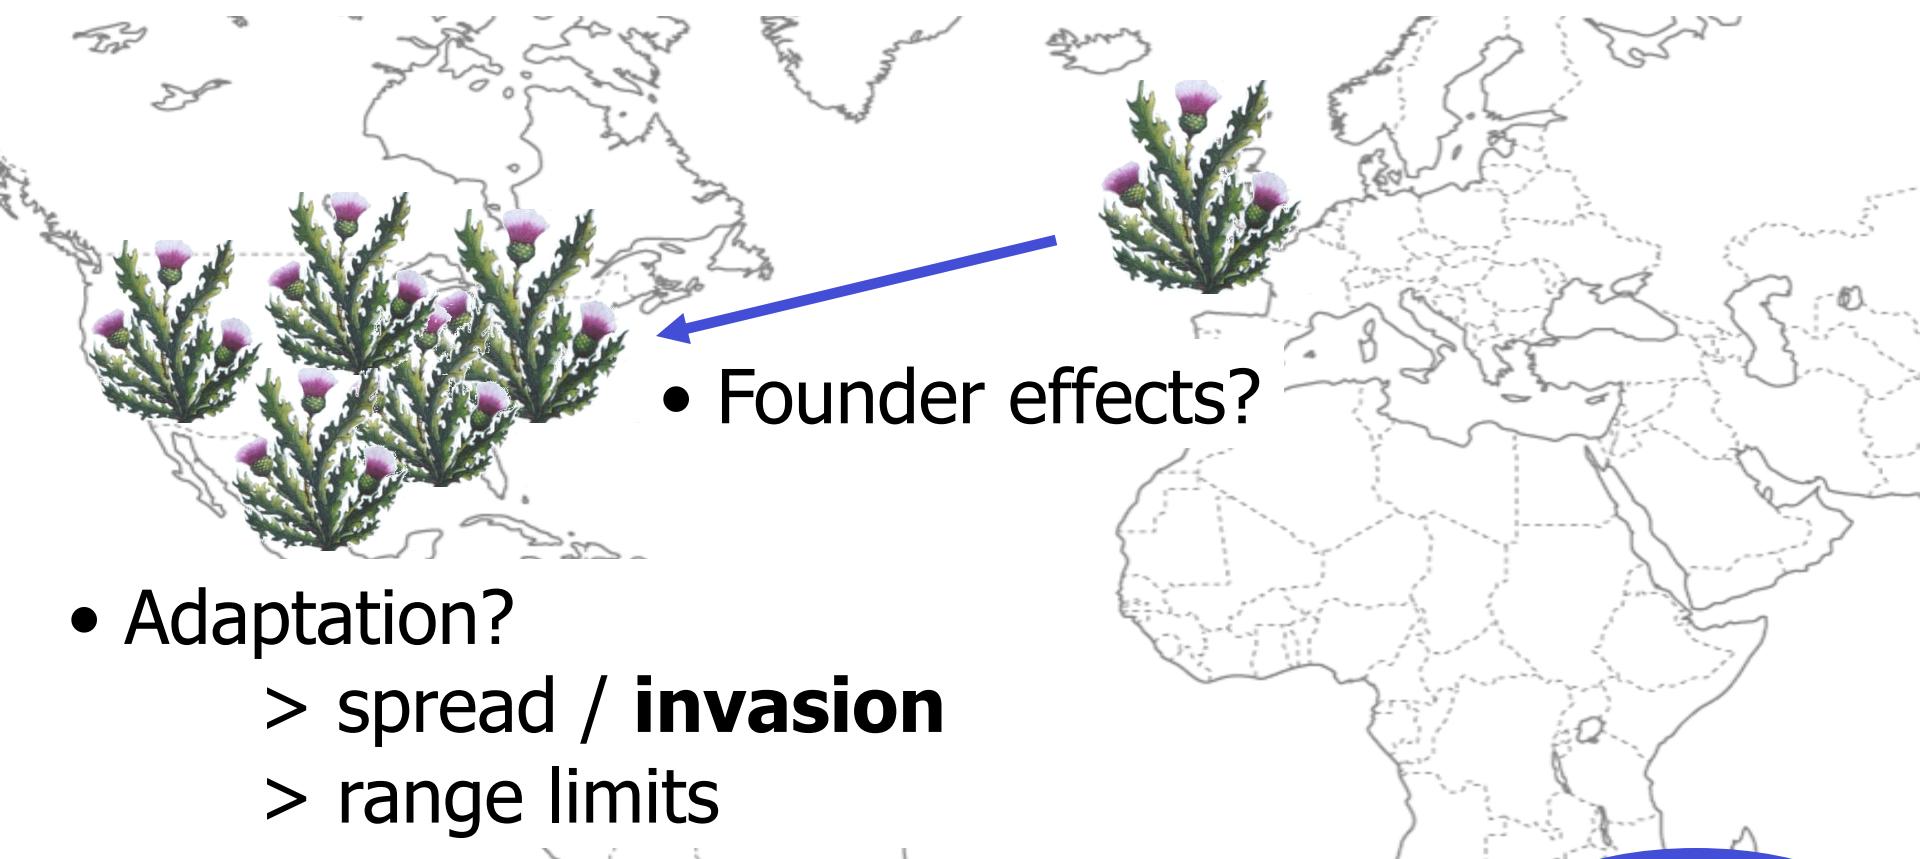

-annual costs of invasive plants to the agricultural community are estimated at \$2.2 billion

(496 are invasive)

# “Natural experiments” in plant evolution

## Introduced species

Transferred outside range of natural dispersal

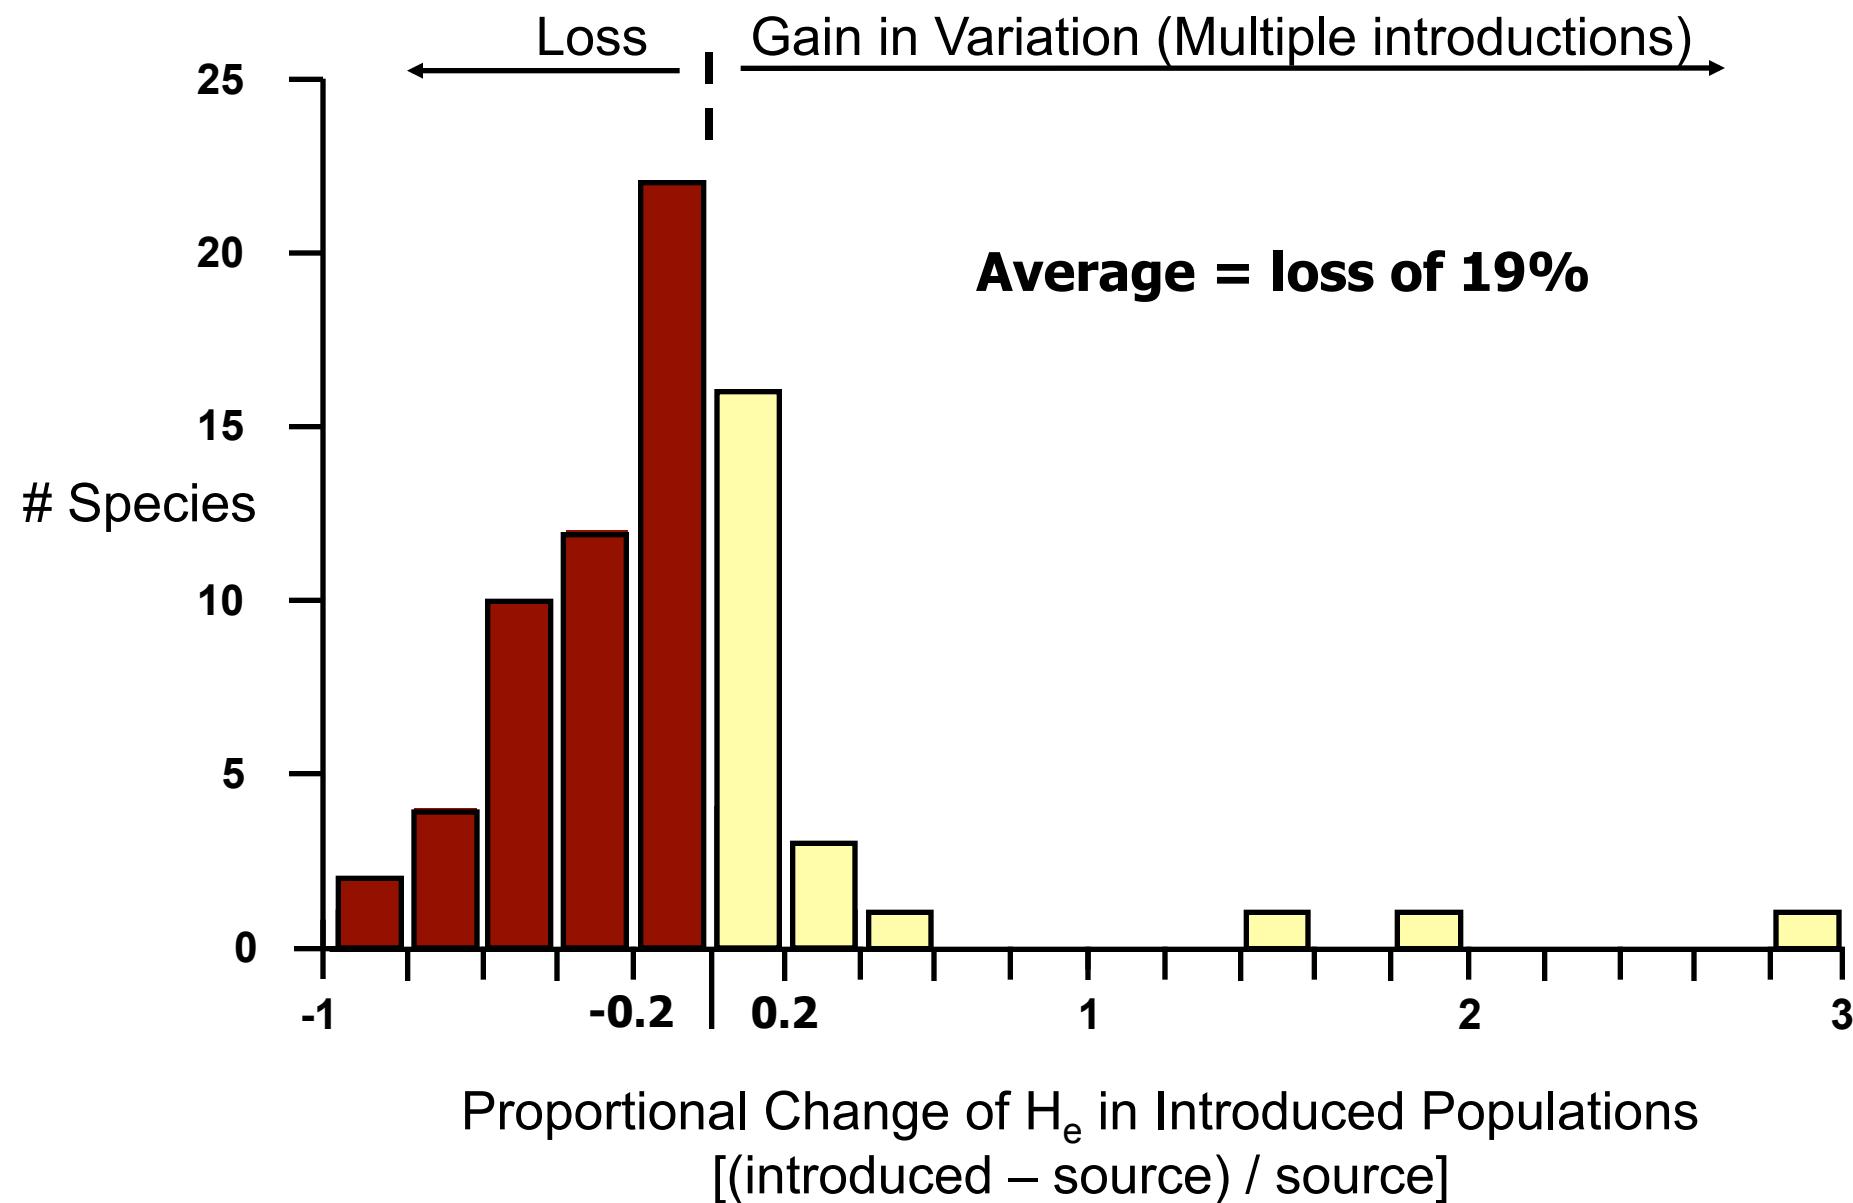

- Founder effects?
- Adaptation?
  - > spread / **invasion**
  - > range limits

= NOT just colonizers of disturbed areas

**WEEDS**

# Founding events: Genetic variation lost

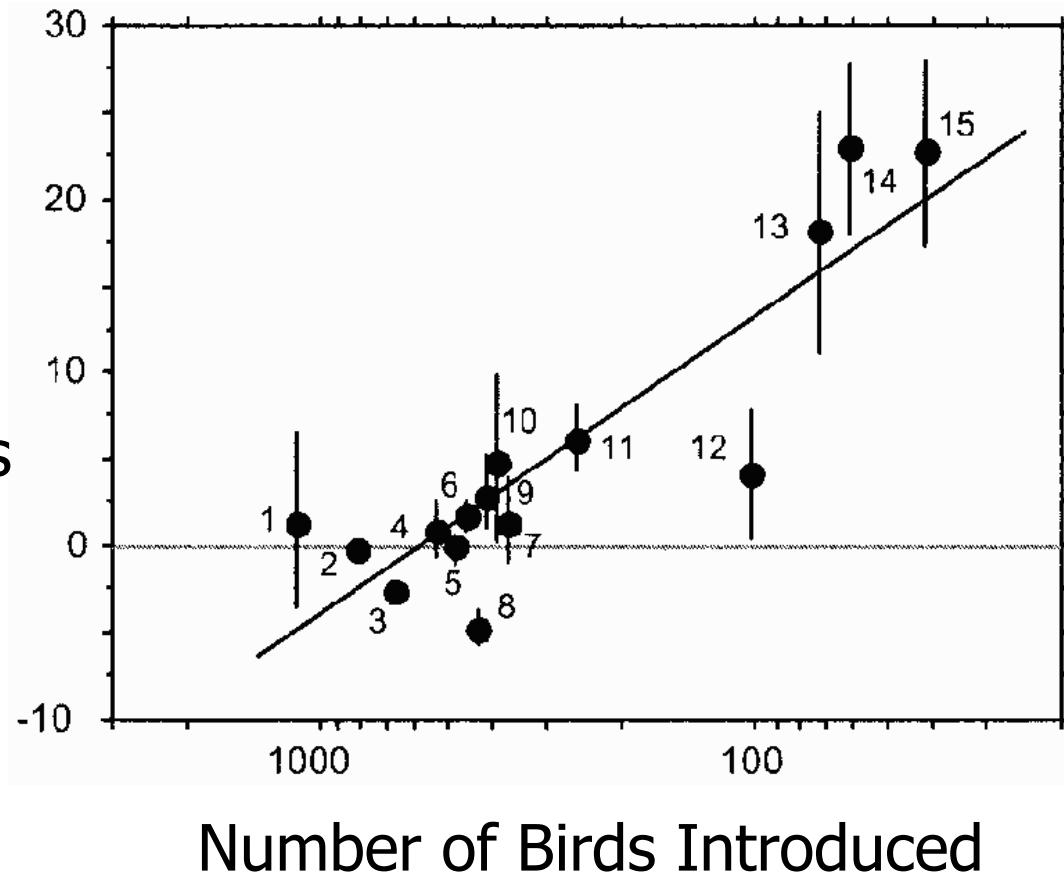

# Founding events

- Genetic bottlenecks probably common
- Non-random mating/asexual reproduction common
  - selfing
  - apomixis (asexual seeds)
  - vegetative spread
- Genetic Drift

# Founding events

We know genetic bottlenecks can have fitness costs

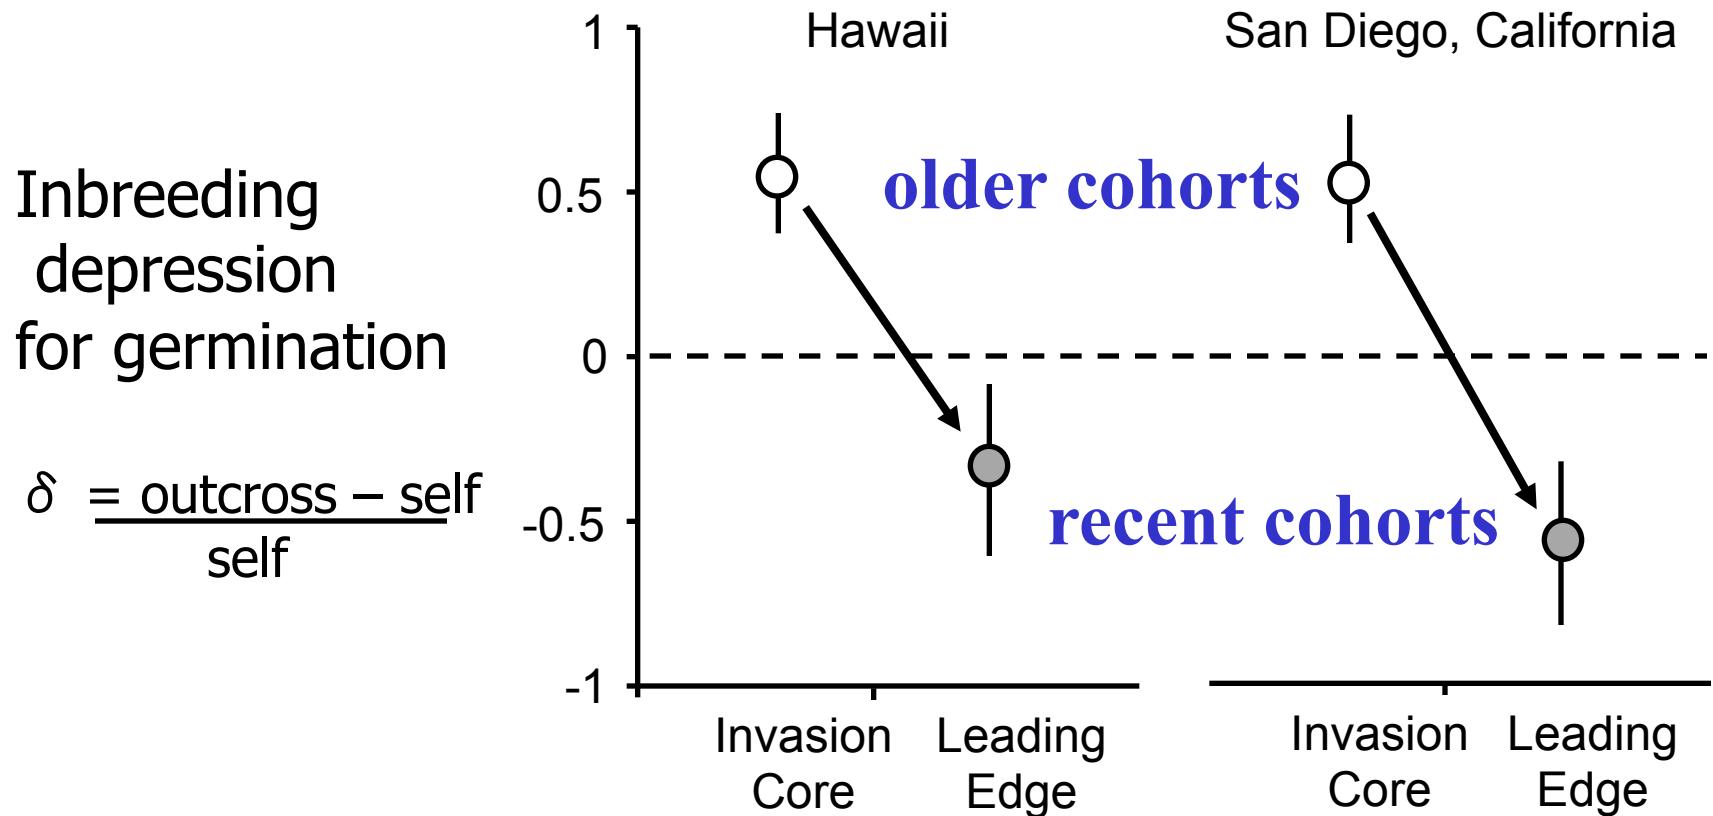

Decline in  
Hatching Success  
vs.  
Source Populations

# Founding events

## Loss of Inbreeding depression in *Hypericum canariense*

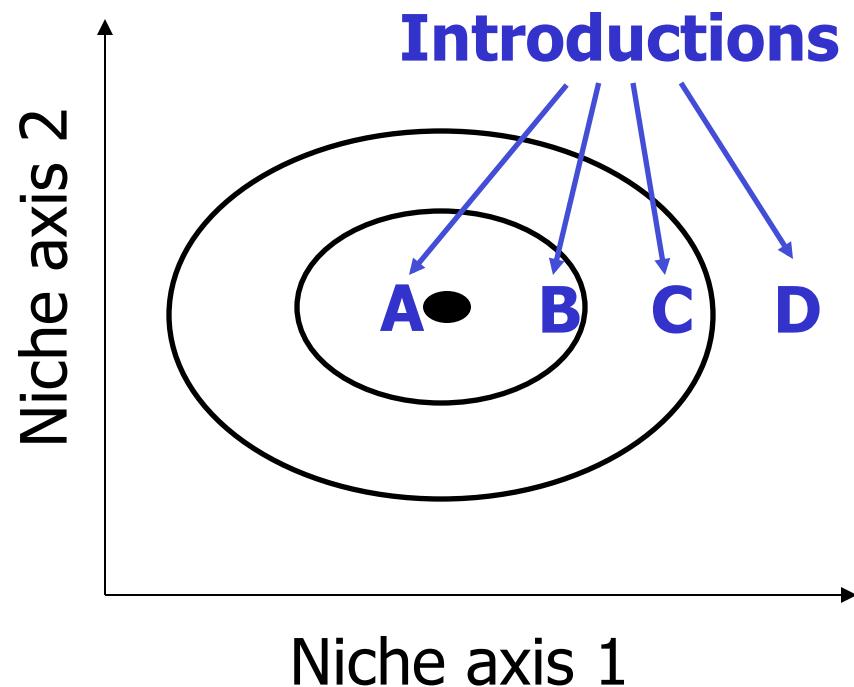

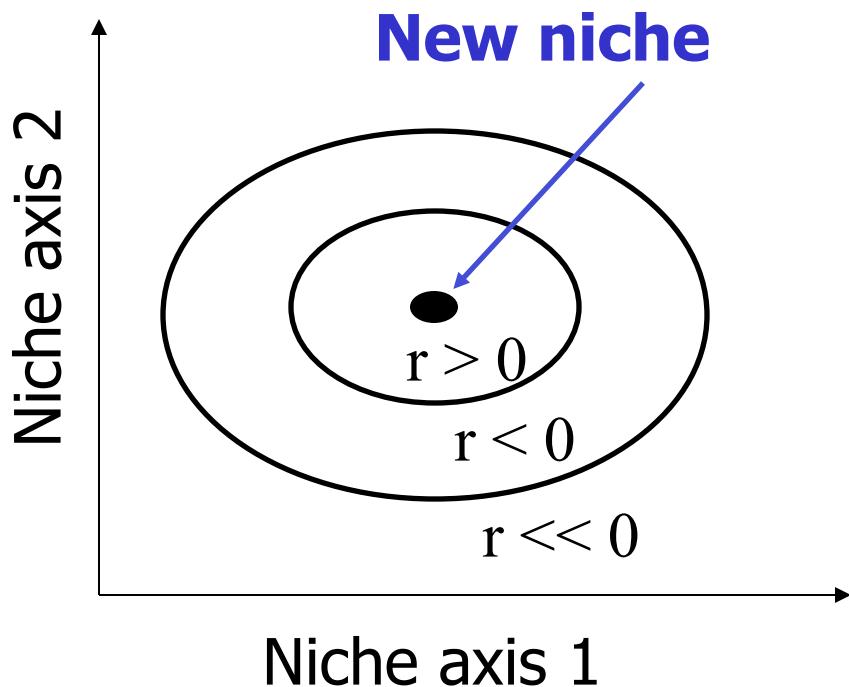

# Adaptation in Introduced Populations

## Depends on:

Genetic variation

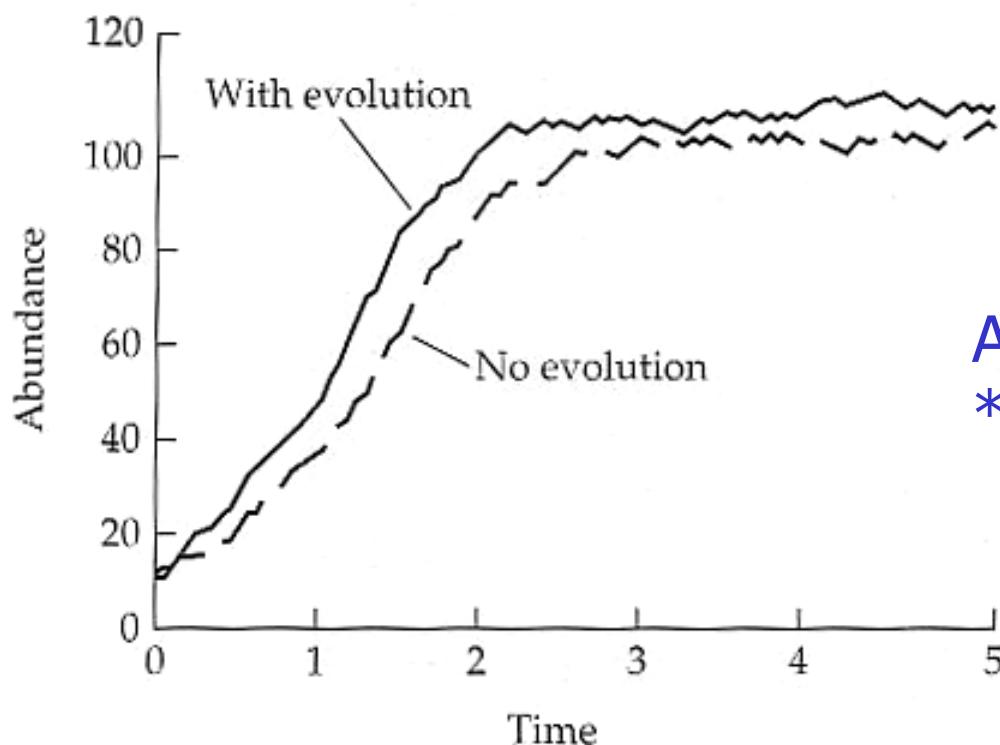

Selection

Extinction risk (population growth,  $r$ )

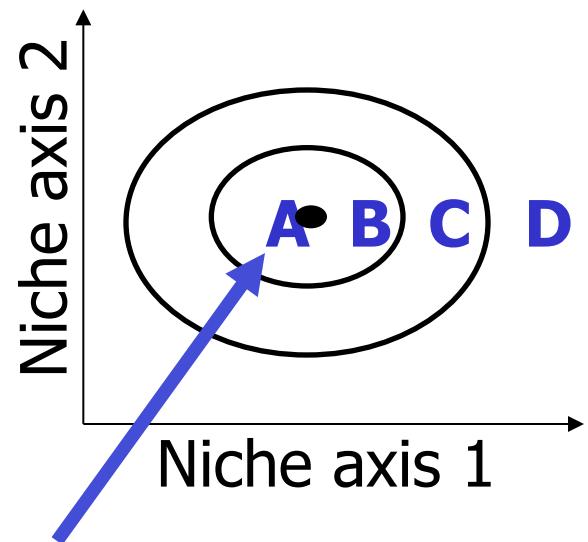

# Adaptation in Introduced Populations

Simulation  
with demographic stochasticity

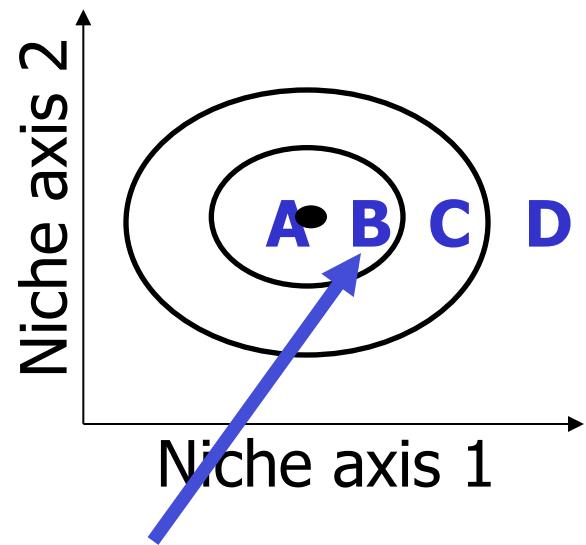

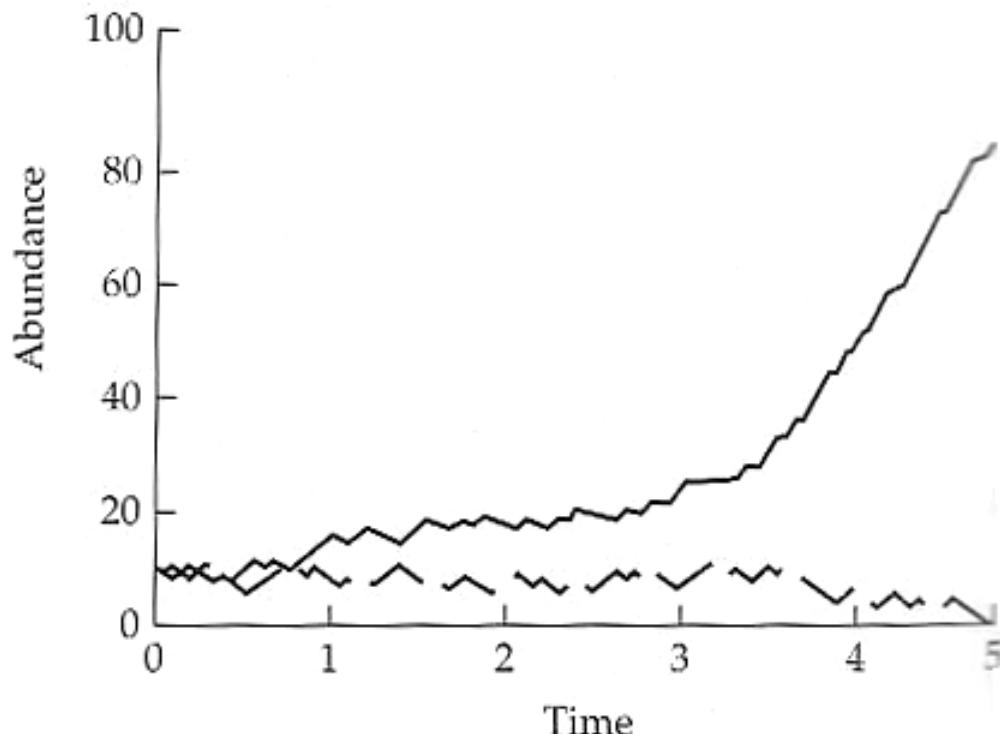

Adaptation occurs  
\*\* NOT required for invasion

# Adaptation in Introduced Populations

Simulation  
with demographic stochasticity

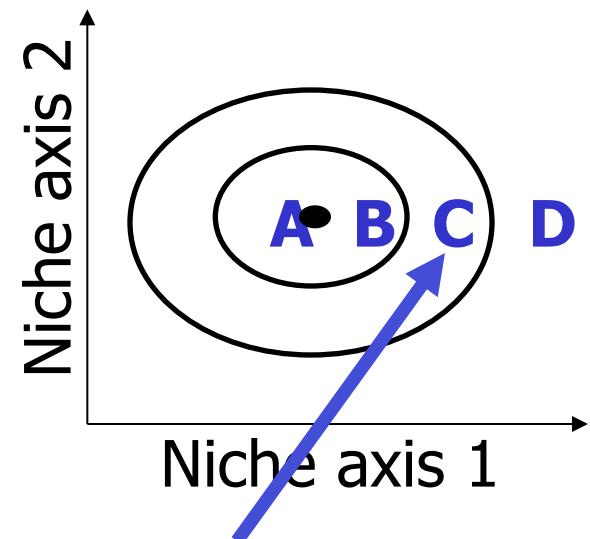

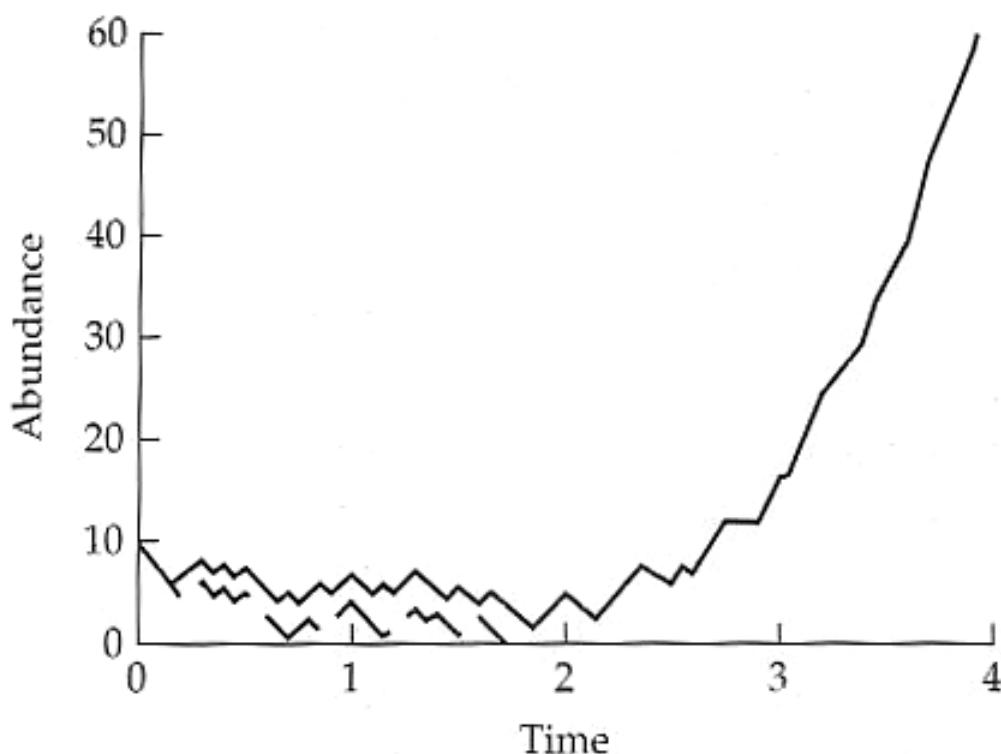

Adaptation beneficial

Produces invasion lag

# Adaptation in Introduced Populations

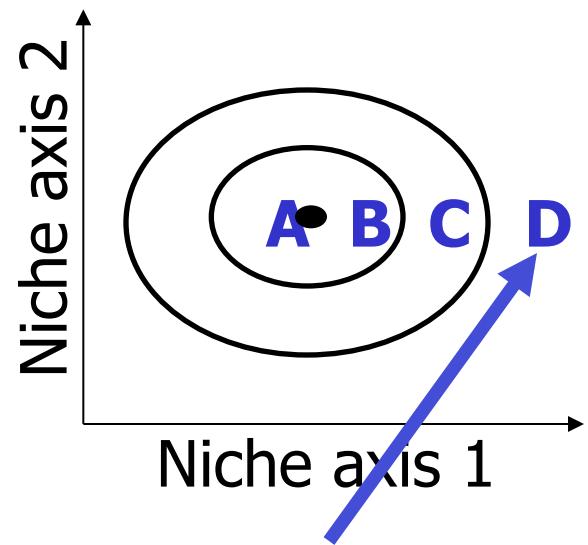

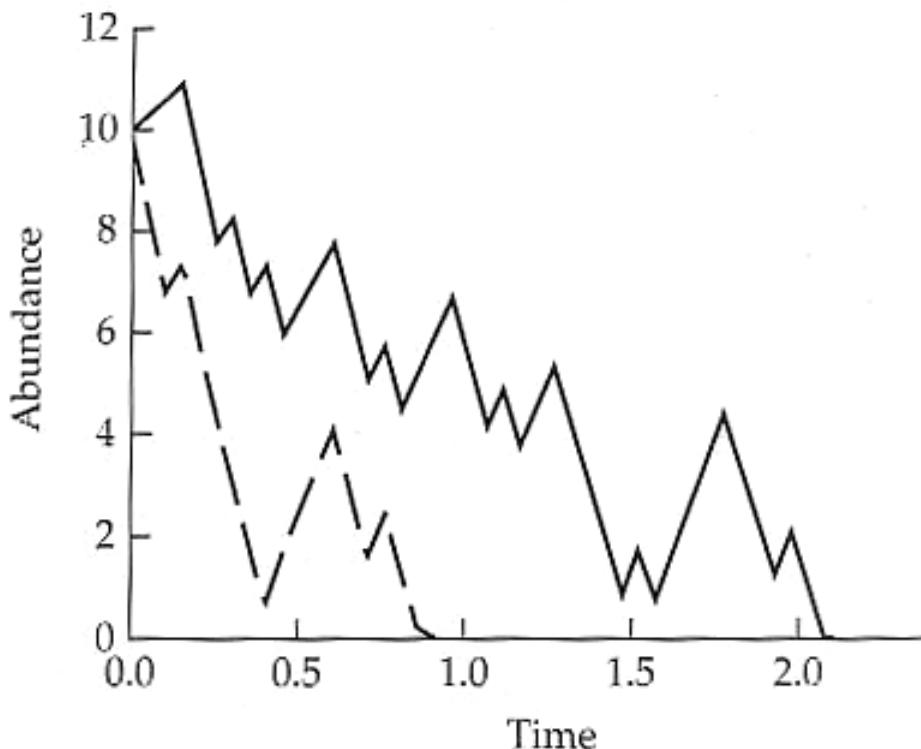

Simulation  
with demographic stochasticity

Adaptation required  
Produces invasion lag

# Adaptation in Introduced Populations

Simulation  
with demographic stochasticity

Adaptation too slow  
to prevent extinction

\*\*hard to study failed  
introductions

# Adaptation in Introduced Populations

## Punchline

The relative difference in environments (niches) occupied by native and invading populations will dictate:

- Extinction risk
- Whether adaptation needed for establishment
- Whether adaptation needed for invasion

# Evolution and invasion

What type of evolutionary changes occur during invasion?

Could these changes contribute to “invasiveness”?

Observation: many plant species grow larger and have greater reproduction and spread more rapidly in the invaded range compared to the native range (Crawley 1987).

Why?

THINK – PAIR - SHARE

# Evolution and invasion

1. Plants trade off investment in self-defence for increased investment in growth and reproduction in the invasive range.
2. Plants trade off tolerance to abiotic stresses in native range for increased competitive and/or colonizing ability.
3. Invasive plants have greater vigor due to hybridization (e.g. heterosis, adaptive introgression, transgressive segregation).

# Common Ragweed (*Ambrosia artemisiifolia*)

1. Do invasive populations have higher growth and reproduction in benign environments compared to native populations?
2. Is any advantage of the invasive populations lost in stressful conditions- i.e. is there evidence for a trade-off?

Goal: compare growth rates, reproductive outputs, stress responses of native and invasive populations of ragweed in common gardens.

# Common Ragweed (*Ambrosia artemisiifolia*)

Wind pollinated, self incompatible  
monoecious annual

Problematic weed native to North America (sunflower, soybean, corn)

Invasive in parts of Australia, Asia and Europe (e.g. 80% of arable land in Hungary is infested)

Severely allergenic (hayfever, dermatitis)

# Distribution of *Ambrosia* over the last 15 000 yrs

# Common garden experimental design

12 invasive, 22 native populations grown in UBC glasshouse

## Experiment 1 - 1278 plants

- 6.4 families/native population
- 9.6 families/invasive population
- Control, light, nutrient, herbivory stress
- 3 blocks

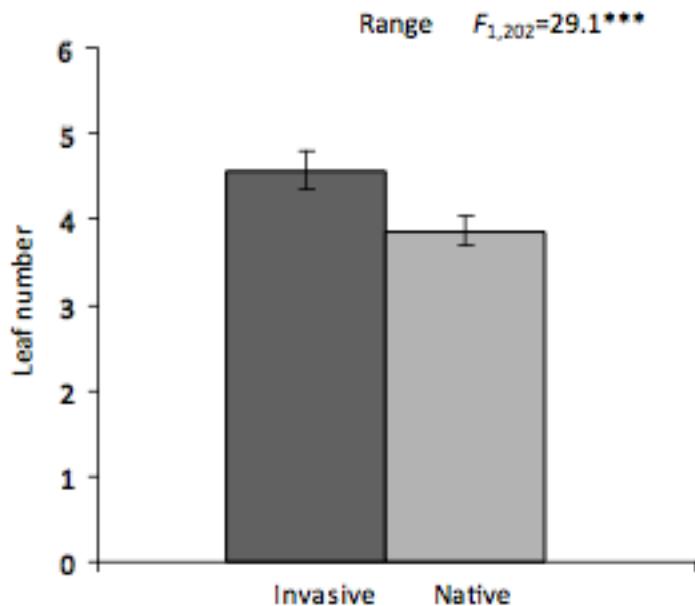

## Experiment 2 - 180 plants

- 3.8 families/native population
- 8.1 families/invasive population
- Drought stress

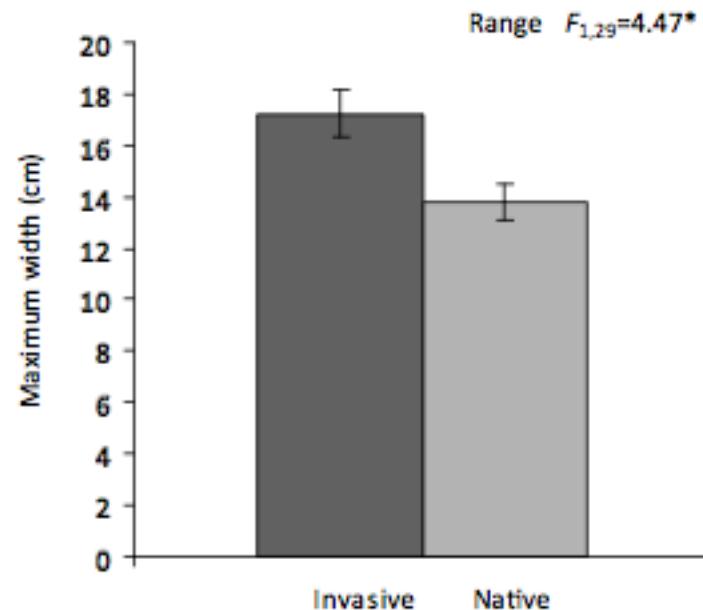

# Initial differences between the native and introduced range

Two weeks after germination

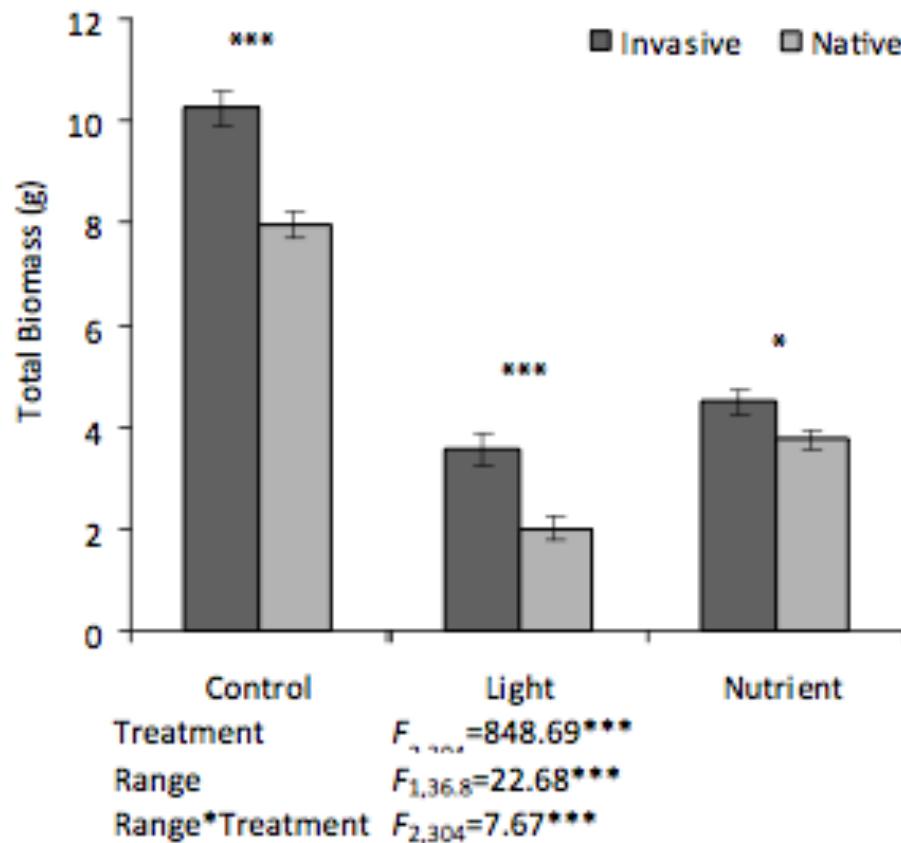

One week after transplant

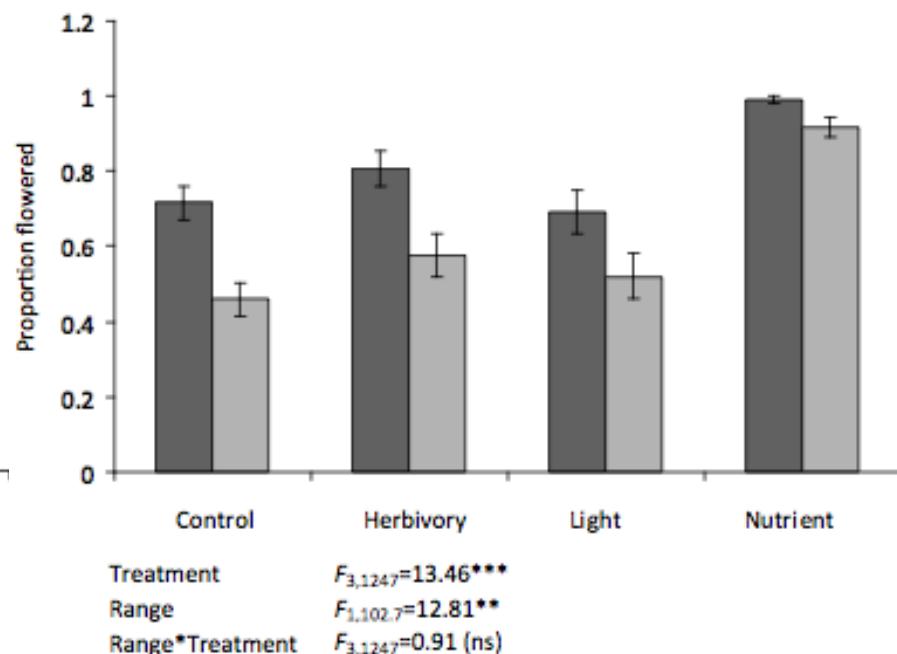

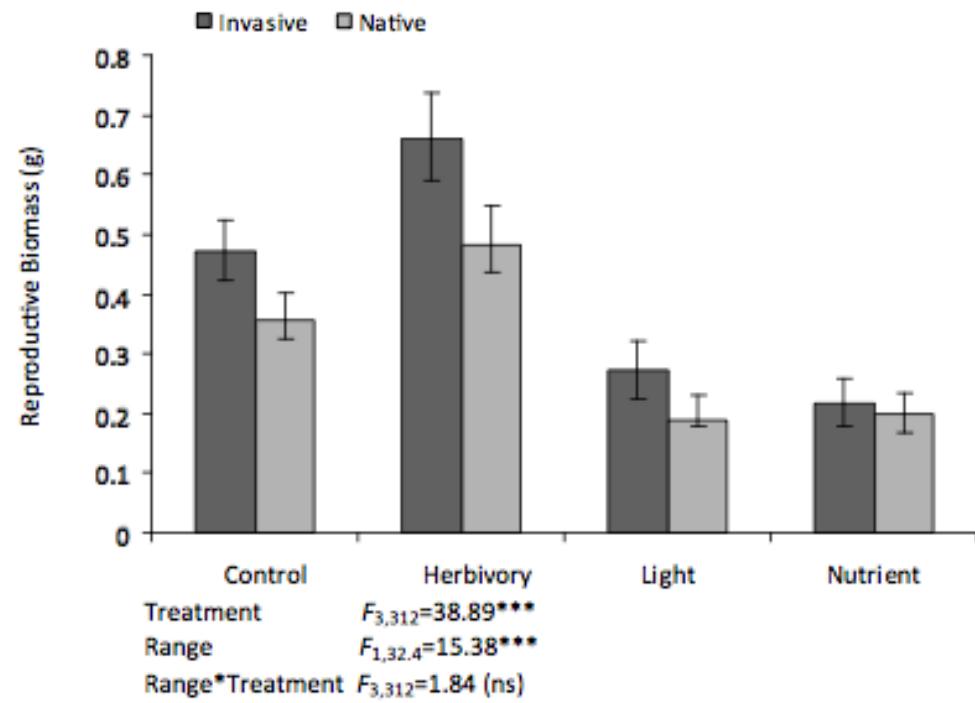

Invasive plants are larger than native plants

# Biomass

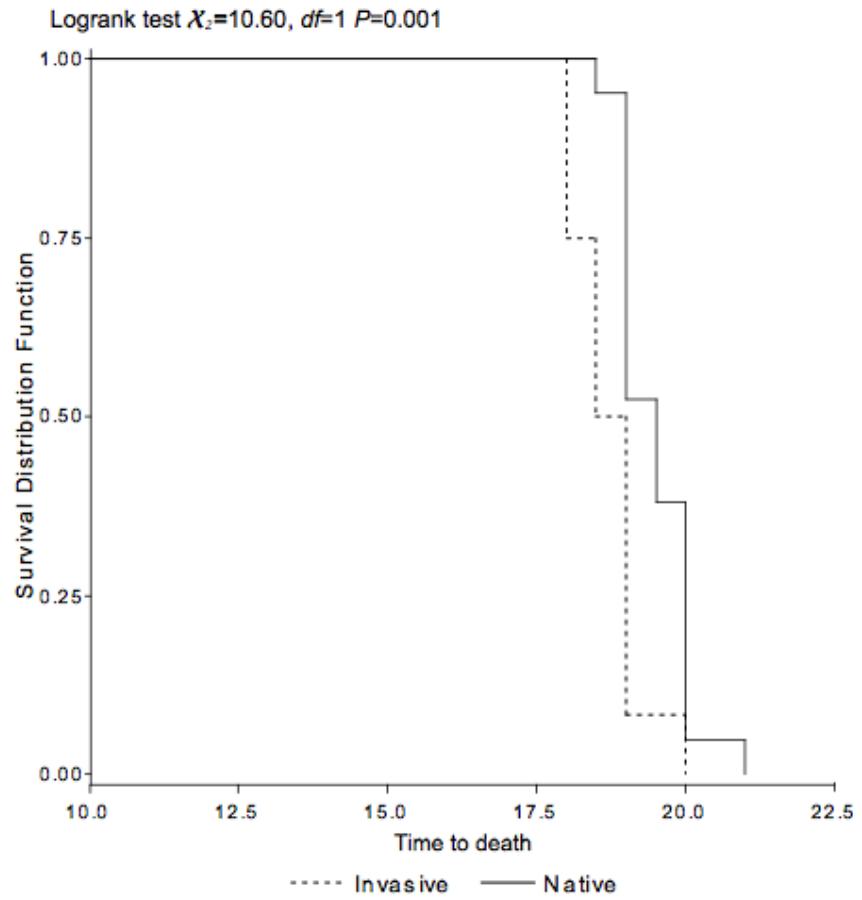

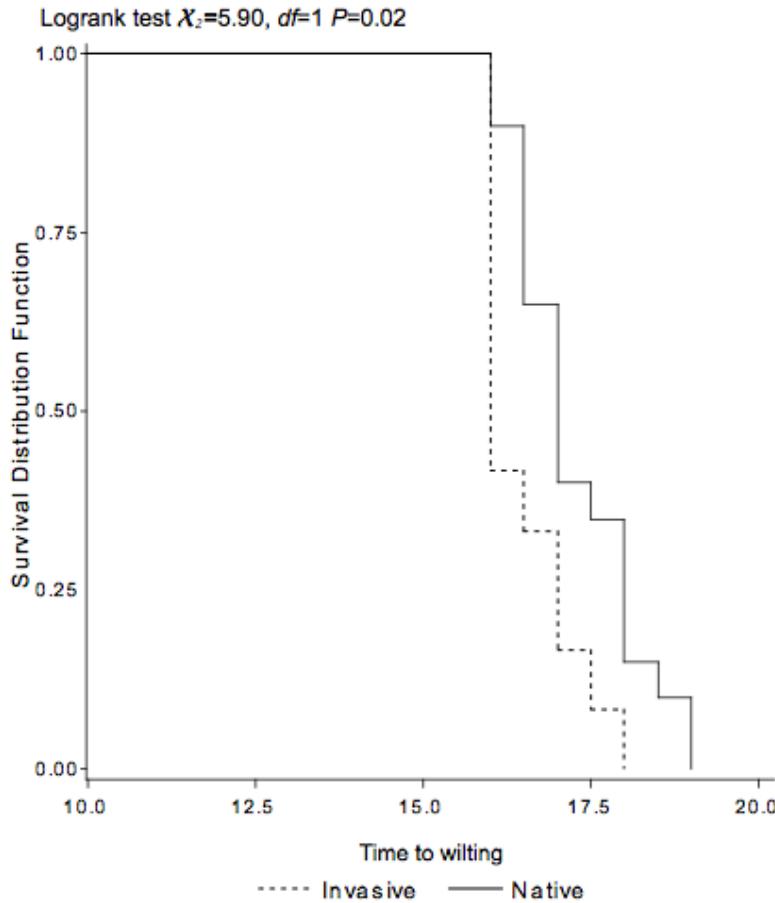

- There is a significant range\*treatment interaction for biomass
- Invasive plants tend to grow larger in the control and light stress
- More equivalent growth in the nutrient stress

# Reproductive success

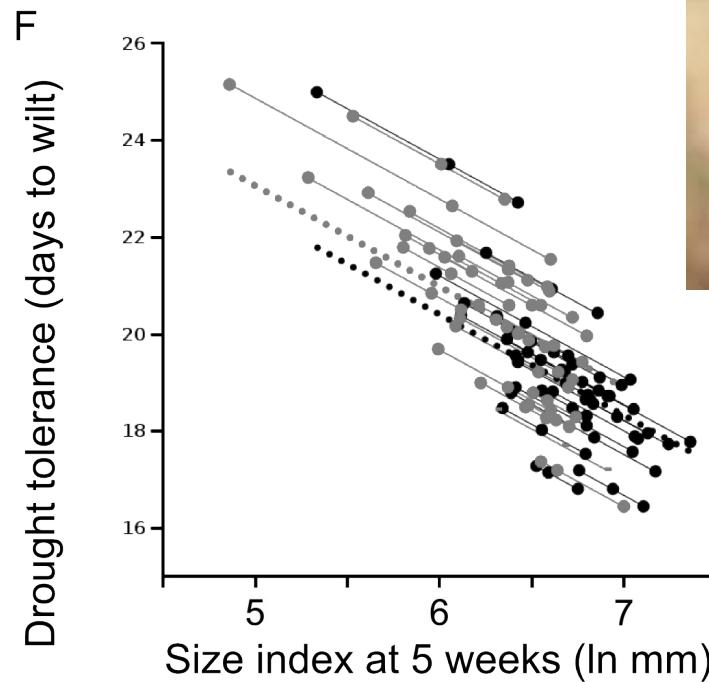

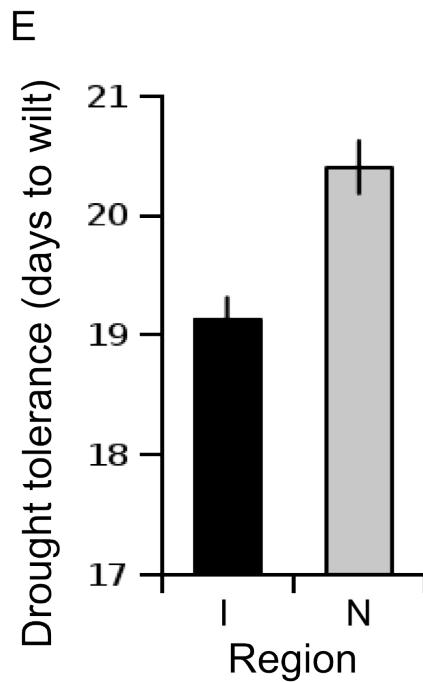

- The invasive plants flowered more frequently and had greater reproductive biomass in all treatments

# Drought Experiment

- Invasive plants wilted and died more quickly than native plants

# More Evolutionary Trade-offs

Evolutionary trade-off between drought tolerance and size  
also seen in yellow starthistle (Dlugosh et al. 2015)

# Conclusions

1. Evolution can be very fast!
2. Biological invasions provide opportunities to study ‘evolution in action’!
3. Genetic bottlenecks are probably common, BUT:
  - Don’t last long (rapid population expansion)
  - Have weak effect on quantitative traits (many genes, many loci)
4. Rapid evolution is important for understanding ecology:
  - Adaptive evolution (usually) increases survival and reproduction – the same parameters that determine population growth.
5. Genetic constraints (e.g. trade-offs) limit the fitness benefits of adaptive evolution. Is this why species have range limits?
